Overview

A solar panel is a device that converts sunlight into electricity by using multiple solar modules that consist of photovoltaic (PV) cells. PV cells are made of materials that produce excited electrons when exposed to light. These electrons flow through a circuit and produce direct current electricity, which can be used to power various devices or be stored in batteries. Solar panels can be used in many ways.

History In 1839, the ability of some materials to create an electrical charge from light exposure was first observed by the French physicist *Edmond Becquerel*. Though these initial solar cells were too inefficient for even simple applications, modern solar modules consist of a large number of solar cells and use light energy from the Sun to generate electricity through the *photovoltaic effect*. Most modules use *silicon*-based cells or *thin-film* cells. Each module is rated by its output power under standard test conditions and hence the on field output power might vary. Power typically ranges from 100 to 365 (W). The efficiency of a module determines the area of a *square meter*.
